MarkovTheory 22/11/2020, 11:02

We have been given $a_i^{pre}(t)$ and $a_{ij}^{post}(t)$, and a Markov Chain X_t . We assume a constant discount factor $v = \frac{1}{1+i}$.

What is the Cash flow induced

We define $I_i(t) = \chi_{X_i=i}$. Which mean that you would get the following annuity at time t: $\sum_{i \in S} a_i^{pre}(t) \times I_i(t).$ Which transition (death) benefit would you get at time t? You get $a_{ij}^{post}(t)$ if you are in state i at time t and in state j at t+1? ie $a_{ij}^{post}(t) \times I_i(t) \times I_j(t+1)$. In sum for the death benefit $\sum_{i,j \in S^2} a_{ij}^{post}(t) \times I_i(t) \times I_j(t+1).$

So the cash flow at times t can be calculated as

$$A(t) = \sum_{i \in S} a_i^{pre}(t) \times I_i(t) + \sum_{i,j \in S^2} a_{ij}^{post}(t) \times I_i(t) \times I_j(t+1)$$

$$\tilde{A}(t) = \sum_{i \in S} a_i^{pre}(t) \times I_i(t) + \sum_{i,j \in S^2} a_{ij}^{post}(t) \times I_i(t) \times I_j(t+1) \times v$$

What is the value of this insurance cash flow?

We define the **Mathematical Reserve** as

$$V_{j}(t) = \mathbb{E}[PV \text{ of future } CF \mid X_{t} = j]$$
$$= \mathbb{E}[\sum_{\tau=0}^{\infty} v^{\tau} \tilde{A}(t+\tau) \mid X_{t} = j]$$

In order to calculate the mathematical reserve you can substitute \tilde{A} in the formula below and ultimately what you need to calculate (keeping in mind the linearity of the $\mathbb E$ functional as the following quantities:

$$\mathbb{E}[I_i(t+\tau)|X_t=j] = p_{ji}(t,t+\tau)$$

$$\mathbb{E}[I_i(t+\tau) \times I_k(t+\tau+1)|X_t=j] = ?$$

How do we do this?

$$\mathbb{E}[I_i(t+\tau) \times I_k(t+\tau+1) | X_t = j] = P[X_{t+\tau+1} = k, X_{t+\tau} = i | X_t = j]$$

MarkovTheory 22/11/2020, 11:02

Now we do the same as in the proof of the Chapman-Kolmogorov-Equation]

$$\begin{split} \mathbb{E}[I_{i}(t+\tau) \times I_{k}(t+\tau+1) | X_{t} = j] &= P[X_{t+\tau+1} = k, X_{t+\tau} = i | X_{t} = j] \\ &= \frac{P[X_{t+\tau+1} = k, X_{t+\tau} = i, X_{t} = j]}{P[X_{t} = j]} \\ &= \frac{P[X_{t+\tau+1} = k, X_{t+\tau} = i, X_{t} = j]}{P[X_{t} = j]} \times \frac{P[X_{t} = j, X_{t+tau} = i]}{P[X_{t} = j, X_{t+tau} = i]} \\ &= P[X_{t+\tau} = i | X_{t} = j] \times P[X_{t+\tau+1} = k | X_{t} = j, X_{t+\tau} = i] \\ &= p_{ii}(t, t+\tau) \times p_{ik}(t+\tau, t+\tau+1) \end{split}$$

If we put now all things together we can calcuate the mathematical reserves as follows

$$\begin{split} V_j(t) &= \mathbb{E}[\sum_{\tau=0}^{\infty} v^{\tau} \tilde{A}(t+\tau) | X_t = j] \\ &= \sum_{\tau=0}^{\infty} v^{\tau} \Biggl(\sum_{i \in S} a_i^{pre}(t+\tau) \times p_{ji}(t,t+\tau) + \sum_{i,j \in S^2} a_{ij}^{post}(t+\tau) p_{ji}(t,t+\tau) \times p_{ik}(t+\tau,t+\tau+1) \right) \end{split}$$

Remark: With this formula we can also calculate the expected cash flows at time t as follows:

$$\mathbb{E}[A(t+\tau) \mid X_t = j] = \sum_{i \in S} a_i^{pre}(t+\tau) \times p_{ji}(t,t+\tau) + \sum_{i,j \in S^2} a_{ij}^{post}(t+\tau) p_{ji}(t,t+\tau) \times p_{ik}(t+\tau,t+\tau)$$

Thiele Difference Equation this is the relationship between the mathematical reserves between times t and t+1. The relationship is as follows:

$$V_j(t) = a_j^{pre}(t) + v \sum_{k \in S} p_{jk}(t, t+1) \times \left(a_{jk}^{post}(t) + V_k(k+1) \right)$$

To prove this equation we split the time-sum into au=0 and the rest. For au=0 we get

$$a_j^{pre}(t) + v \sum_{k \in S} p_{jk}(t, t+1) \times a_{jk}^{post}(t)$$

as per above.

In a second step we need to consider (NEW AND IMPROVED FORMULA:)

$$\sum_{\tau=1}^{\infty} v^{\tau} \left(\sum_{i \in S} a_i^{pre}(t+\tau) \times p_{ji}(t,t+\tau) + \sum_{(i,k) \in S^2} a_{ij}^{post}(t+\tau) p_{ji}(t,t+\tau) \times p_{ik}(t+\tau,t+\tau+1) \times v \right)$$

$$= \sum_{\tau=1}^{\infty} v^{\tau} \sum_{i \in S} p_{ji}(t,t+\tau) \times \left(a_i^{pre}(t+\tau) + \sum_{k \in S} a_{ij}^{post}(t+\tau) p_{ik}(t+\tau,t+\tau+1) \times v \right)$$

MarkovTheory 22/11/2020, 11:02

We can now calculate the quantity $p_{ji}(t, t + \tau)$ as follows, by means of the Chapman-Kolmorgorov equation

$$p_{ji}(t, t + \tau) = \sum_{l \in S} p_{jl}(t, t + 1) \times p_{li}(t + 1, t + \tau)$$

$$\sum_{\tau=1}^{\infty} v^{\tau} \left(\sum_{i \in S} a_i^{pre}(t+\tau) \times p_{ji}(t,t+\tau) + \sum_{i,j \in S^2} a_{ij}^{post}(t+\tau) p_{ji}(t,t+\tau) \right)$$

$$= \sum_{\tau=1}^{\infty} v^{\tau} p_{ji}(t,t+\tau) \times \left(\sum_{i \in S} a_i^{pre}(t+\tau) + \sum_{i,j \in S^2} a_{ij}^{post} \right)$$

$$= \sum_{\tau=1}^{\infty} v^{\tau} \left(\sum_{l \in S} p_{jl}(t,t+1) \times p_{li}(t+1,t+\tau) \right) \times \left(\sum_{i \in S} a_i^{pre}(t+\tau) + \sum_{i,j \in S^2} a_{ij}^{post} \right)$$

$$= \sum_{t \in S} p_{jl}(t,t+1) \times v \times \left(\sum_{\tau=0}^{\infty} v^{\tau} p_{li}(t+1,t+1+\tau) \times \left(\sum_{i \in S} a_i^{pre}(t+1+\tau) + \sum_{i,j \in S^2} a_{ij}^{post}(t+1+\tau) \right) \right)$$

Remarks:

- 1) For one life we have a recursion of reals $A_x = q_x \times v + p_x \times v \times A_{x+1}$. In case of MR of a Markov model we have a recursion of vectors.
- 2) To solve it one needs boundary conditions as per before with $V_j(\omega)=0\ \forall j\in S$
- 3) Thiele Difference Equations leads to the same results as for the classical life insurance we have seen.
